

Mobile and Embedded Computing

Laboratory 5.

Task I

1. Define a data model class (e.g., ``User`` or ``Post``) using the ``json_annotation`` package and generate the ``fromJson`` / ``toJson`` serialization code using ``build_runner`` and ``json_serializable``.
2. Integrate the ``equatable`` package into your model class to enable deep equality comparisons.
3. Instantiate two separate objects with the exact same data and demonstrate that they are considered equal by printing the result of the ``==`` comparison. (Make screenshots while doing this, in order to quickly verify the completion of this step).

Task II

1. Use a Flutter HTTP library (such as `dio` or `package:http`) to fetch data from a public REST API (e.g., JSONPlaceholder) and map the JSON response to your generated model from Task I.
2. Implement a retry mechanism using exponential backoff and jitter to handle network or server errors. Deliberately trigger a failure (e.g., by targeting an invalid endpoint) and observe the retries and increasing delays in your application logs. (Make screenshots while doing this, put them in a Word document).
